God's Programming Book

Lecture-25 Declarative Programming

Declarative Programming

Slides Adapted from cs61a of UC Berkeley

Declarative Languages

Database Management Systems

Database management systems (DBMS) are important, heavily used, and interesting!

A table is a collection of records, which are rows that have a value for each column

			,	- 1	
A table has columns and rows	Latitude	Longitude	Name		A column has a name and a type
co camino ana rows	38	122	Berkeley		Traine and a cype
A row has a value for each column	42	71	Cambridge		
Tor cacir cocamir	45	93	Minneapolis		

The Structured Query Language (SQL) is perhaps the most widely used programming language

SQL is a declarative programming language

Declarative Programming

In declarative languages such as SQL & Prolog:

- A "program" is a description of the desired result
- The interpreter figures out how to generate the result In **imperative languages** such as Python & Scheme:
- A "program" is a description of computational processes
- The interpreter carries out execution/evaluation rules

Cities:

latitude	longitude	name
38	122	Berkeley
42	71	Cambridge
45	93	Minneapolis

create table cities as		
select 38 as latitude,	122 as longitude,	"Berkeley" as name union
select 42,	71,	"Cambridge" union
select 45,	93,	"Minneapolis";

region	name
west coast	Berkeley
other	Minneapolis
other	Cambridge

```
select "west coast" as region, name from cities where longitude >= 115 union select "other", name from cities where longitude < 115;
```

Structured Query Language (SQL)

SQL Overview

The SQL language is an ANSI and ISO standard, but DBMS's implement custom variants

- A select statement creates a new table, either from scratch or by projecting a table
- A create table statement gives a global name to a table
- Lots of other statements exist: **analyze**, **delete**, **explain**, **insert**, **replace**, **update**, etc.
- Most of the important action is in the select statement

Getting Started with SQL

Install sqlite (version 3.8.3 or later):

http://sqlite.org/download.html

Use sqlite online:

code.cs61a.org/sql

Selecting Value Literals

A **select** statement always includes a comma-separated list of column descriptions

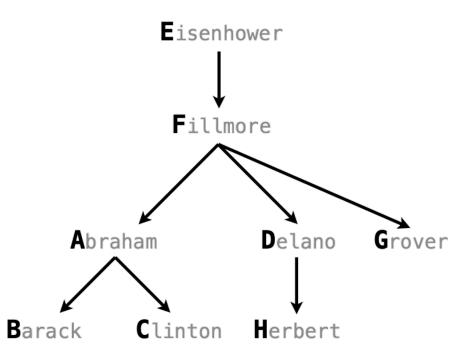

A column description is an expression, optionally followed by as and a column name

```
select [expression] as [name], [expression] as [name];
```

Selecting literals creates a one-row table

The union of two select statements is a table containing the rows of both of their results

```
select "delano" as parent, "herbert" as child union
                          , "barack"
select "abraham"
                                               union
select "abraham"
                          , "clinton"
                                               union
                          , "abraham"
                                               union
select "fillmore"
                          , "delano"
select "fillmore"
                                               union
select "fillmore"
                          , "grover"
                                               union
select "eisenhower"
                         , "fillmore";
```

Naming Tables

```
SQL is often used as an interactive language

The result of a select statement is displayed to the user, but not stored

A create table statement gives the result a name
```

```
create table [name] as [select statement]:
                                                                     Eisenhower
create table parents as
  select "delano" as parent, "herbert" as child union
                                                                      Fillmore
  select "abraham"
                           , "barack"
                                                 union
  select "abraham"
                           , "clinton"
                                                 union
                           , "abraham"
  select "fillmore"
                                                 union
                                                             Abraham
                                                                             Delano
                                                                                       Grover
                           , "delano"
  select "fillmore"
                                                 union
  select "fillmore"
                           , "grover"
                                                 union
                                                                   Clinton
                                                                             erbert
                                                        Barack
  select "eisenhower"
                           "fillmore":
```

Naming Tables

SQL is often used as an interactive language

The result of a **select** statement is displayed to the user, but not stored

A **create table** statement gives the result a name

create table [name] as [select statement];

create table parents as

```
select "delano" as parent, "herbert" as child union
select "abraham"
                         , "barack"
                                              union
select "abraham"
                         , "clinton"
                                              union
                         , "abraham"
select "fillmore"
                                              union
                         , "delano"
select "fillmore"
                                              union
                         , "grover"
select "fillmore"
                                              union
select "eisenhower"
                         "fillmore":
```

Parents:

Parent	Child
abraham	barack
abraham	clinton
delano	herbert
fillmore	abraham
fillmore	delano
fillmore	grover
eisenhower	fillmore

Projecting Tables

Select Statements Project Existing Tables

A select statement can specify an input table using a **from** clause

A subset of the rows of the input table can be selected using a **where** clause

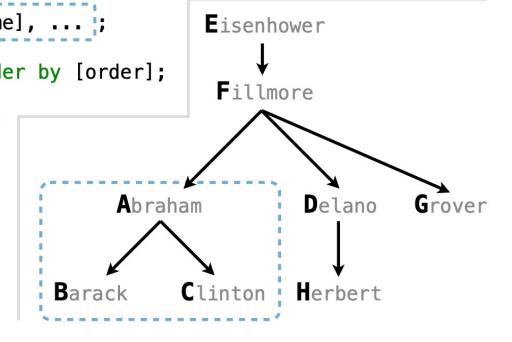

An ordering over the remaining rows can be declared using an **order by** clause

Column descriptions determine how each input row is projected to a result row

select [expression] as [name], [expression] as [name], ...;
select [columns] from [table] where [condition] order by [order];
select child from parents where parent = "abraham";
select parent from parents where parent > child;

Child	
barack	
clinton	

Parent
fillmore
fillmore

Arithmetic

Arithmetic in Select Expressions

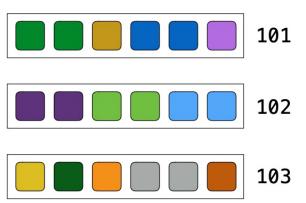

In a select expression, column names evaluate to row values

Arithmetic expressions can combine row values and constants

select chair, single + 2 * couple as total from lift;

chair	total
101	6
102	6
103	6

Thanks for Listening
