Abstraction

Functional Abstractions

def square(x):
 return mul(x, x)

def sum_squares(x, y):
 return square(x) + square(y)

What does sum_squares need to know about square?

- Square takes one argument. Yes.
- Square has the intrinsic name square. No.
- Square computes the square of a number. Yes.
- Square computes the square by calling mul. No.

Functional Abstractions

If the name "square" were bound to a built-in function, sum_squares would still work identically.

Choosing Names

Names typically don't matter for correctness

but

they matter a lot for composition

From:	To:
true_false	rolled_a_one
d	dice
helper	take_turn
my_int	num_rolls
l, I, O	k, i, m

- Names should convey the meaning or purpose of the values to which they are bound.
- The type of value bound to the name is best documented in a function's docstring.
- Function names typically convey their effect (print),
 their behavior (triple), or the value returned (abs).

Which Values Deserve a Name

Reasons to add a new name

Repeated compound expressions:

```
if sqrt(square(a) + square(b)) > 1:
    x = x + sqrt(square(a) + square(b))

hypotenuse = sqrt(square(a) + square(b))
if hypotenuse > 1:
    x = x + hypotenuse
```

• Meaningful parts of complex expressions:

```
x1 = (-b + sqrt(square(b) - 4 * a * c)) / (2 * a)

discriminant = square(b) - 4 * a * c
x1 = (-b + sqrt(discriminant)) / (2 * a)
```

Which Values Deserve a Name

More Naming Tips

• Names can be long if they help document your code:

```
average_age = average(age, students)
is preferable to
# Compute average age of students
aa = avg(a, st)
```

• Names can be short if they represent generic quantities: counts, arbitrary functions, arguments to mathematical operations, etc.

```
n, k, i - Usually integers
x, y, z - Usually real numbers
f, g, h - Usually functions
```

Thanks for Listening
